TEMPORARY PONDS
A NATURAL HABITAT TO BE PROTECTED!

“CONSERVATION OF TEMPORARY PONDS IN THE SOUTHWEST COAST OF PORTUGAL”
LIFE12NAT/PT/997

www.lifecharcos.lpn.pt
The species of fauna and flora colonizing temporary ponds – many of which considered rare and endangered – are adapted to the specific ecological conditions of this habitat, namely the seasonality of available water, being a typical feature of the Mediterranean climate. Thus, these species have the ability to survive underwater during months, and afterwards endure conditions of extreme draught.

The diversity of life in a temporary pond is very high and generally greater than the one found in other freshwater habitats, such as permanent pools or water courses. The spatial and temporal dynamics determine the pond species composition and zonation.

In early spring it is possible to find fluctuating water plants with the leaves and flowers on the surface. Amphibious plants then appear, which begin their vegetal development still underwater and bloom only when the pond begins to dry, thus persisting until the arrival of the dry season (beginning of summer).

In terms of fauna, the temporary ponds are used as feeding and reproduction zone by several species of amphibians, reptiles, mammals and invertebrates, being crucial for the existence of various uncommon species of limited distribution, such as amphibians and Large Branchiopoda crustaceans.

### Biodiversity of the Mediterranean Temporary Ponds

- **Iberian spadefoot toad** ([Pelobates cultripes](#))
  - Photo: Luis Guilherme Souza

- **European Pond Turtle** ([Emys orbicularis](#))
  - The largest national populations of this freshwater reptile are found in the temporary ponds of the southwest coast.
  - In Portugal they have the conservation status of “Endangered”.

- **Bats**
  - These flying mammals visit the temporary ponds in different times of the year, having greater activity during the flooded season, during which they come up to drink water and feed on the enormous amount of flying insects.
  - The *Myotis daubentoni* – Daubentons’s bat (in the photo) can capture insects landed on the water surface.

- **Cabrera’s Vole** ([Microtus cabrerae](#))
  - This is the only endemic rodent of the Iberian Peninsula.
  - It uses the tall grass found in the surroundings of the temporary ponds as feeding areas.

- **European Pond Turtle** ([Emys orbicularis](#))
  - The largest national populations of this freshwater reptile are found in the temporary ponds of the southwest coast.
  - In Portugal they have the conservation status of “Endangered”.

- **Biodiversity that "adds colour" to temporary ponds:**
  - Plants
  - Amphibians
  - Crustaceans
  - Reptiles
  - Mammals

- These flying mammals visit the temporary ponds in different times of the year, having greater activity during the flooded season, during which they come up to drink water and feed on the enormous amount of flying insects.

- The Myotis daubentonii – daubentons bat (in the photo) can capture insects landed on the water surface.

---

**EuropEan pond TurTlE (Emys orbicularis)**

- The largest national populations of this freshwater reptile are found in the temporary ponds of the southwest coast.

- In Portugal they have the conservation status of ‘endangered’.

---

**souThErn marB lEd nEwT (Triturus pygmaeus)**

- This amphibian is an iberian endemic species.

- It uses temporary ponds for reproduction, preferring sites with plenty of aquatic vegetation. The females place each egg under a broad leaf, in a total of 150-350 eggs.

---

**Eryngium corniculatum**

- The leaves of this plant have two distinct shapes: when the pond is flooded they are thick and hollow, and when the pond begins to dry they become firm and rigid.

- An indicator species of the priority habitat 3170*.

---

**parslEy frog (Pelodytes sp.)**

- It prefers temporary ponds as reproduction sites.

- There is a suspicion that the amphibians of the Pelodytes genus in the southwestern region of Portugal belong to a distinct genetic lineage, although this has not been completely clarified.

---

**fairy shrimp (in the photo: Branchipus cortesi)**

- These large Branchiopoda have the ability to swim ‘upside down’, and some of the species have life cycles of only 15 days, being fully adapted to the ephemeral nature of these ecosystems.

---

**CaBrEra’s volE (Microtus cabrerae)**

- This is the only endemic rodent of the Iberian Peninsula.

- It uses the tall grass found in the surroundings of the temporary ponds as feeding areas.

---

**souThErn Europe**

**Biodiversity that ‘adds Colour’ to temporary ponds:**

- Plants
- Amphibians
- Crustaceans
- Reptiles
- Mammals

---

**ISOetes setaceum**

- A flowerless plant that reproduces itself through spores instead of seeds. The sporangia – organs that produce and contain the spores – are not covered by any kind of membrane.

- An indicator species of the priority habitat 3170* with the ‘near threatened’ status in the IUCN red list.

---

**TAPOLE SHRIMP (in the photo: Triops cancriformis)**

- The Triops cancriformis is the most emblematic species of the ephemeral ecosystems of the farthest southwest regions of Portugal, having been described in 2010.

- Their presence is registered in temporary ponds since the late Triassic – Early Jurassic period, the age of dinosaurs.

---

**TadpolE shrimp (in the photo: Triops vicentinus)**

- The Triops vicentinus, the most emblematic species of these large Branchiopoda, is an endemic species of the farthest southwest regions of Portugal, having been described in 2010.

- Their presence is registered in temporary ponds since the late Triassic – Early Jurassic period, the age of dinosaurs.
Temporary ponds appear in depressions along the upper layer of the soil during the first occurrences of rain of the hydrological year, where the rainwater is accumulated due to the existence of a soil layer inside the ponds (with a lower permeability than the surrounding soils) that favours water retention. The first flooding occurrences are ephemeral, since these first waters end up infiltrating and evaporating. However, these ponds are hydraulically connected to subterranean waters, and from the moment the groundwater level reaches and surpasses the base elevation of the pond, the water storing period becomes longer. Thus, the hydroperiod of most of these ponds, although seasonal, is higher than the corresponding simple accumulation of rainwater on the depressions of soils with low permeability.
The Project LIFE + ‘Conservation of Temporary Ponds in the Southwest Coast of Portugal’ (LIFE12NAT/PT/997), whose acronym is LIFE Charcos, intends to support and promote the conservation of Mediterranean Temporary Ponds. These ponds are increasingly endangered due to their ecological fragility and to the unawareness of their natural value.

The singularity of this habitat is associated to the diversity and peculiarity of the hosted organisms. Some of the present species, namely some freshwater crustaceans, are endemic* and have a very restricted distribution area.

During a long time, the Mediterranean Temporary Ponds were dominating elements of the South-western Portuguese landscape, and their conservation was compatible with the traditional and extensive soil uses. However, the last two decades witnessed their degradation and accentuated regression of the distribution area.

Through this project we intend to reduce the observed declining trend of temporary ponds and promote the recovery of ponds in unfavourable conservation conditions.

*Endemism: taxon (species, genus, etc.) whose geographical distribution is restricted to a certain geographic area.
GOALS OF THE PROJECT

The Project LIFE Charcos intends to improve the conservation status of temporary ponds in Southwestern Portugal by fulfilling the following goals:

• Compilation of the available biological data and update the cartography;
• Promote the reduction and elimination of identified threats;
• Demonstrate management and restoration techniques that improve the conservation status of this habitat;
• Establish a seed bank (page 15), as a tool for conservation and restoration actions, and as plant biodiversity safeguarding;
• Promote dissemination of knowledge on the ecology and function of this habitat, on a local basis, by demonstrating sustainable management practices;
• Contribute towards long term protection of this habitat by engaging landowners, farmers, decision makers, and other interested parties;
• Raise public awareness about the conservation needs of this habitat and about the value of the ecosystem.

INTERVENTION AREA

The Project LIFE Charcos shall be implemented at the Site of Community Importance (SCI) of the Southwest Coast within the Natura 2000 Network (partially overlapping the Natural Park of Southwest Alentejo and Costa Vicentina – PNSACV). The main areas are specifically located in coastal plateau of Odemira and Vila do Bispo municipalities, where one may find the main concentrations of known Mediterranean Temporary Ponds in Portugal.

The SCI of the Southwest Coast is located along the coastline of the Iberian Peninsula and it includes areas from the municipalities of Sines, Odemira, Aljezur and Vila do Bispo. This area is also designated as a costal plateau due to its slightly undulated relief and absence of sharp slopes - except for the valleys near the water lines.

At a national level, this area is of the utmost importance, since it contains some habitats considered as biodiversity hotspots, which are vital for many rare and endangered species.

This SCI also accommodates an extraordinary natural heritage, which includes the Mediterranean Temporary Ponds, along with their flora and fauna. Such heritage may be used to boost sustainable local development, namely sustainable tourism.
This priority habitat is increasingly endangered due to the course of anthropogenic actions, ecological fragility and unawareness of its natural value. This has specifically been the case of the SCI of the Southwest Coast, where over the last two decades industrialized agriculture and tourism have caused an accelerated decline of this habitat.

Traditionally seen as unproductive areas, the temporary ponds are currently subject to intensive farming techniques, such as deep soil tillage, drainage, irrigation and fertilization of cultures in the vicinity of the ponds, surface earthworks and transformation in permanent irrigation reservoirs.

The threats over this habitat also include tourism pressure, forestation, vehicle circulation, overgrazing or absence of grazing, invasive species and climate change.

The great biological and ecological value of this habitat is simply ignored by the majority of the population. This unawareness and the lack of information represent also a threat to its conservation.

4 THREATS TO THE CONSERVATION OF TEMPORARY PONDS AND THEIR BIODIVERSITY

Changes in the agricultural and livestock practices

- a) tillage,
- b) drainage,
- c) excavation for construction of permanent reservoirs,
- d) irrigation of cultures,
- e) overgrazing or absence of grazing,
- f) fertilization (nutrient input) and use of agrochemicals, and
- g) invasive species (flora and fauna).

Threats to conservation

- Habitat fragmentation
- Impoverishment of the related biodiversity
- Lack of information/unawareness
- Touristic pressure
- Forestry activity
- Climate change
5 ACTIONS WITHIN THE PROJECT
LIFE CHARCOS

1 - PREPARATORY ACTIONS
The preparatory actions shall consolidate the scientific knowledge on the hydrological functioning and biological diversity of temporary ponds.

The compilation of data, along with a cartography update, and its integration within a GIS (Geographic Information System) will assist management decisions.

This project also intends to establish evaluation criteria regarding the conservation status of temporary ponds, in order to create an index that allows assessing its conservation status and set out directives for its management.

2 - SPECIFIC CONSERVATION ACTIONS

2.1) Management of a favourable conservation status for temporary ponds
Some temporary ponds have a reasonable conservation status, and in these cases light interventions might be a decisive contribution towards their long term conservation.

Therefore, the project intends to avoid soil drainage and deep tillage, and restrict the access of cattle, resorting to fences and water troughs.

Such actions will work as a practical demonstration of management measures, which may be used in future agro-environmental commitments.

2.2) Actions for recovery and/or restoration of temporary ponds
Being a pioneering effort in Portugal, the intention is to rehabilitate and recover the degraded temporary ponds, thus promoting the re-establishment of biophysical conditions that allow their long term maintenance.

The foreseen interventions include reconstructing the topographical profile of the ponds, removing the invasive flora and re-establishing the characteristic pond flora.

2.3) Recovery of a temporary pond to raise awareness
Due to their particular characteristics, temporary ponds allow the performance of different activities and may even serve as real ‘open space laboratories’.

The recovery of a temporary pond for educational purposes – which would be accessible to the general population – would serve as an example of ecological restoration. This action is the combination of two main goals: on one hand, the recovery of a pond in a symbolic area of this habitat, and on the other, the promotion of widespread knowledge by raising the awareness of the general population about the importance of its conservation.

2.4) Establishment and maintenance of a seed bank
The Mediterranean Temporary Ponds are increasingly rare, and the unique vegetal species that characterize them may disappear along with them.

The ex-situ preservation of plant diversity may be achieved on the long term by establishing a seed bank.

The collection and conservation of germplasm – seeds and other propagulum – represent
an important repository for safeguarding the species in these environments. Many of these species are only found in these habitats and their inclusion in a seed bank will allow their use to support restoration actions, thus ensuring their future availability and conservation of the Mediterranean Temporary Ponds.

2.5) Promotion of extensive grazing
Both overgrazing and the absence of grazing cause changes in the vegetation cover, which have a very negative effect in the conservation of the habitat. The promotion of extensive grazing intends to demonstrate the benefits of this practice in the maintenance and conservation of temporary ponds.

2.6) Promotion of habitat connectivity
The temporary ponds of the Southwest Coast occur in clusters, thus resulting in an aggregation of ponds.

A disturbance in one pond – besides disrupting it – may also cause a decrease in the connectivity between an entire system of ponds.

Therefore, the project intends to prove the efficiency of using simple and inexpensive measures – which do not hinder other soil uses – in minimizing the effects of fragmentation in the biodiversity associated to temporary ponds, and thus promote the movement and interchange of specimens between ponds.

2.7) Nature Stewardship Network
The main purpose of a Nature Stewardship Network is to raise awareness and promote an active participation in conservation, as well as to encourage the correct use of natural, cultural and/or landscape resources. This project seeks to unite the various stakeholders that may directly or indirectly support a Nature Stewardship Network for the Mediterranean Temporary Ponds. Stewardship agreements or “Commitment Letters” will be settled, which shall function as voluntary statements of intent regarding the protection of this habitat.

3 – Environmental awareness and disclosure of results
The general public is not aware of the great biological and ecological value of temporary ponds. This unawareness is the greatest indirect threat to its conservation. Raising awareness amongst the populations in the distribution area of this habitat is crucial towards its preservation and to ensure its long term conservation. This action will be directed to particular key groups, such as landowners and farmers, but also to children and young students, as well as to the general public.

Projeto LIFE Charcos (contract LIFE12NAT/PT/997)
“Conservation of Temporary Ponds in the Southwest Coast of Portugal”
Coordinating beneficiary: Liga para a Protecção da Natureza (LPN) [Nature Protection League]
Associated beneficiaries: University of Évora (LPN), University of Algarve (IJL), Municipality of Odemira (CMO) and Association of Beneficiaries of Mira (ABM)
Duration: 1st of July 2013 until 31st of December 2017
Total budget of the Project: 1 977 465€ (European Union contribution of 75%)
The LIFE Programme is the EU funding instrument for the environment. The general goal of LIFE is to contribute towards the implementation, updating and development of the EU environmental policy and of the legislation for pilot projects or demonstration of European added value. The LIFE – Nature programme in particular co-funds projects seeking to restore and conserve endangered habitats and protect priority conservation species within EU.

Natura 2000 – Europe’s nature for you!
This project was implemented within the European Natura 2000 Network. The fact that it includes some of the most endangered species and habitats in Europe was the reason for its selection. All 28 countries of the European Union are working together for the Natura 2000 Network in order to protect the diverse and rich natural heritage of Europe for the benefit of all.
